Background Information

- Designs of quantum systems (e.g., quantum robots) must be verified, tested, and validated
- Formally verify these designs via quantum model checking
- Carry out quantum model checking on invariants of quantum automata.
- Extend this to verify safety properties for reversible automata
- Extend this to verify ω -properties for reversible Büchi automata
- Meet requirements for correctness, safety, & reliability

Problem Statement

- Verify functional correctness of quantum systems.
- Input: Description of system behavior
 - i.e., specifications based on quantum automata
- Input: Functional linear-time properties
 - Linear-time invariants of quantum automata-based model
- Output: Boolean flag indicating correct/incorrect system behavior/functionality.

Shortcomings of Traditional Model Checking

- Cannot formalize behavior/functionality of quantum systems
 - Discrete state spaces of classical systems are finite or countably finite
 - Continuous state spaces of quantum systems cannot be addressed by discrete state spaces
 - State spaces of quantum systems are continuous, even for finite-dimensional quantum systems
- Cannot formally describe temporal properties of quantum systems

Additional Formal Verification Techniques for Quantum Robots (1)

- Reachability analysis:
 - Possible solution: Quantum partially-observable Markov decision processes (QMDPs)

- Quantum Equivalence Checking:
 - Given 2 models of a quantum robot, determine if they are functionally equivalent.
 - Use quantum information decision diagrams (QuIDD), global-phase equivalence, and relative-phase equivalence (Viamontes et al., 2009).
 - Ditto for tensor calculus, dynamic tensor products, partial

Additional Formal Verification Techniques for Quantum Robots (2)

- SMT-based quantum formal verification:
 - Use SMT solver (decision procedure for satisfiability modulo theories) as reasoning engine for formal verification
 - Use reasoning/computational engine for hybrid model checking and theorem proving or model checking and equivalence checking
 - Use fragments of 1st-order logic, such as differential dynamic logics, for hybrid systems verification; see work by Prof. André Platzer at <http://symbolaris.com/>.
 - Get the quantum logic equivalent of these.

Additional Formal Verification Techniques for Quantum Robots (3)

- Exploit equivalence of maximum satisfiability (Max-SAT), pseudo-boolean optimization (PBO), and weighted PBO:
 - ① Use meta-algorithms via algorithmic portfolio optimization to select the “best” or set of good solutions (Max-SAT, Max-SMT, PBO, or Weighted PBO).
 - ② Engineer quantum logic variant/equivalent.
 - ③ Turn numerical models in the time domain to algebraic models in the frequency domain, via transform methods (e.g., Fourier transform, Laplace transform, and z-transform) and approximations via parameterization and (quasi-) linearization
 - ④ The meta-algorithms enable us to plug-and-play (or plug-and-pray) components for quantum formal verification.

- Use Quantum Model Order Reduction for Approximation:
 - ① Quantum Model Order Reduction approximates components of quantum robots as continuous-time dynamical systems.
